

How the Grass sim will work

In short it will first ask the user to input how much land they got to grow

How much land do you have?

x

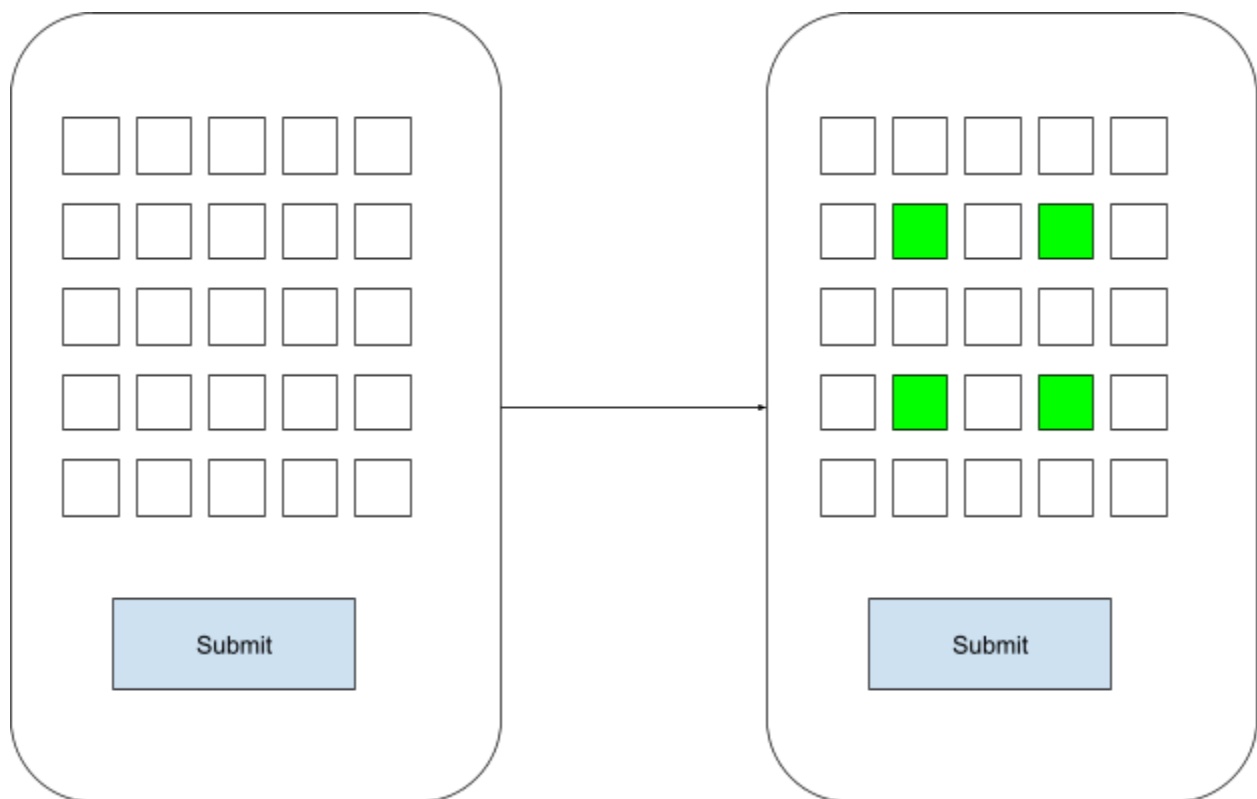

Submit

Once the user enters the amount of land they have, a grid will be created the amount of land they have, indicated by little grids

So for example if the user has 10 X 10 pieces of land a grid of land of 1 x 1 per grid shows up. But the bigger the land, the more adjusted the land grid will be.

- Maybe every 20 inches bigger the more the grid box can have
 - 1 x 1 → 2 x 2 → 3 x 3 → etc.
- This could be helpful, but we also need to find imperfections as well, so maybe it will be adjusted an extra .5 for those?
 - 1 x 1 → 1 x 1.5 → etc.
 - 1 x 1 → 1.5 x 1 → etc.

From here the user will click on the grids that will be grass planted spots

Once the user has selected the area they want, they can then pick from any type of grass that exists. Which will then fully cover the area in the amount of time, and amount of grass it will cost them according to grass prices and so much more

Current tester, my dad. Even though he might already have got the item he needs, it never hurts to see how he can navigate a simple application like this. Can also help me see where I can tweak in the process.

The application will also simulate the growing process to see how much grass will be covered. This shows how much it grows and if there are any small patches with no grass, where to improve from the last areas.

The user is able to go back to the grass selection area so they can adjust the area

Current Languages

- React
 - From what is right now, the only big thing that I will need is to react, but if other languages will be used ill state it in the read me.
